

Introduction to Spring JDBC

Using JdbcTemplate

Objectives

After completing this lesson, you should be able to

- Explain the problems with traditional JDBC
- Use and configure Spring's **JdbcTemplate**
- Execute queries using callbacks to handle result sets
- Handle Exceptions

Agenda

- Problems with Traditional JDBC
- Spring's `JdbcTemplate`
- Lab
- Optional Slides

Redundant, Error Prone Code in Traditional JDBC code

```
public List<Person> findByLastName(String lastName) {  
    List<Person> personList = new ArrayList<>();  
    String sql = "select first_name, age from PERSON where last_name=?";  
  
    try (Connection conn = dataSource.getConnection();  
        PreparedStatement ps = conn.prepareStatement(sql)) {  
        ps.setString(1, lastName);  
  
        try (ResultSet rs = ps.executeQuery()) {  
            while (rs.next()) {  
                personList.add(new Person(rs.getString("first_name"), ...));  
            }  
        }  
    } catch (SQLException e) {  
        /* ??? */  
    }  
  
    return personList;  
}
```

Redundant, Error Prone Code in Traditional JDBC code

```
public List<Person> findByLastName(String lastName) {  
    List<Person> personList = new ArrayList<>();  
    String sql = "select first_name, age from PERSON where last_name=?";  
  
    try (Connection conn = dataSource.getConnection();  
        PreparedStatement ps = conn.prepareStatement(sql)) {  
        ps.setString(1, lastName);  
  
        try (ResultSet rs = ps.executeQuery()) {  
            while (rs.next()) {  
                personList.add(new Person(rs.getString("first_name"), ...));  
            }  
        }  
    } catch (SQLException e) {  
        /* ??? */  
    }  
  
    return personList;  
}
```

The bold matters - the
rest is *boilerplate*

Redundant, Error Prone Code in Traditional JDBC code

```
public List<Person> findByLastName(String lastName) {  
    List<Person> personList = new ArrayList<>();  
    String sql = "select first_name, age from PERSON where last_name=?";  
  
    try (Connection conn = dataSource.getConnection();  
        PreparedStatement ps = conn.prepareStatement(sql)) {  
        ps.setString(1, lastName);  
  
        try (ResultSet rs = ps.executeQuery()) {  
            while (rs.next()) {  
                personList.add(new Person(rs.getString("first_name"), ...));  
            }  
        }  
    } catch (SQLException e) {  
        /* ??? */  
    }  
  
    return personList;  
}
```

How do you handle low-level
SQLException?

Agenda

- Problems with Traditional JDBC
- Spring's `JdbcTemplate`
 - Introduction
 - Basic Usage
 - Working with result sets
 - Exception handling
- Lab
- Optional Slides

Template Design Pattern

- Widely used and useful pattern
 - http://en.wikipedia.org/wiki/Template_method_pattern
- Define the outline or skeleton of an algorithm
 - Leave the details to specific implementations later
 - Hides away large amounts of *boilerplate* code
- Spring provides many template classes
 - `JdbcTemplate`, `JmsTemplate`
 - `RestTemplate`, `WebServiceTemplate` ...
 - Most hide low-level resource management

Spring's JdbcTemplate

- Greatly simplifies use of the JDBC API
 - Eliminates repetitive boilerplate code
 - Alleviates common causes of bugs
 - Handles **SQLExceptions** properly
- Without sacrificing power
 - Provides full access to the standard JDBC constructs

“Life is too short to write JDBC!”

- Rod Johnson co-founder of Spring

JdbcTemplate in a Nutshell

```
int count = jdbcTemplate.queryForObject(  
    "SELECT COUNT(*) FROM CUSTOMER", Integer.class);
```

- Acquisition of the connection
- Participation in the transaction
- Execution of the statement
- Processing of the result set
- Handling exceptions
- Release of the connection

**All handled
by Spring**

Using Callbacks

```
List<Customer> results = jdbcTemplate.query(someSql,  
    new RowMapper<Customer>() {  
        public Customer mapRow(ResultSet rs, int row) throws SQLException {  
            // map the current row to a Customer object  
        }  
    });
```

```
class JdbcTemplate {  
    public List<Customer> query(String sql, RowMapper rowMapper) {  
        try {  
            // acquire connection  
            // prepare statement  
            // execute statement  
            // for each row in the result set  
            results.add(rowMapper.mapRow(rs, rowNumber));  
            return results;  
        } catch (SQLException e) {  
            // convert to root cause exception  
        } finally { /* release connection */ }  
    }  
}
```

Callback
method

Creating a JdbcTemplate

- Requires a **DataSource**

```
JdbcTemplate template = new JdbcTemplate(dataSource);
```

- Create a template once and re-use it
 - Do not create one for each thread
 - Thread safe after construction
- Uses
 - *Anytime* JDBC is needed
 - In utility or test code
 - To clean up messy legacy code

Agenda

- Problems with Traditional JDBC
- Spring's **JdbcTemplate**
 - Introduction
 - **Basic Usage**
 - Working with Result Sets
 - Exception Handling
- Lab
- Optional Slides

Implementing a JDBC-based Repository

```
public class JdbcCustomerRepository implements CustomerRepository {  
  
    private JdbcTemplate jdbcTemplate;  
  
    public JdbcCustomerRepository(DataSource dataSource) {  
        this.jdbcTemplate = new JdbcTemplate(dataSource);  
    }  
  
    public int getCustomerCount() {  
        String sql = "select count(*) from customer";  
        return jdbcTemplate.queryForObject(sql, Integer.class);  
    }  
}
```

No try / catch needed
(unchecked exceptions)

Querying with JdbcTemplate

- **JdbcTemplate** can query for
 - Simple types (int, long, String, Date, ...)
 - Generic Maps
 - Domain Objects

Query for Simple Java Types

- Query with no bind variables

```
public Date getOldest() {  
    String sql = "select min(dob) from PERSON";  
    return jdbcTemplate.queryForObject(sql, Date.class);  
}  
  
public long getPersonCount() {  
    String sql = "select count(*) from PERSON";  
    return jdbcTemplate.queryForObject(sql, Long.class);  
}
```

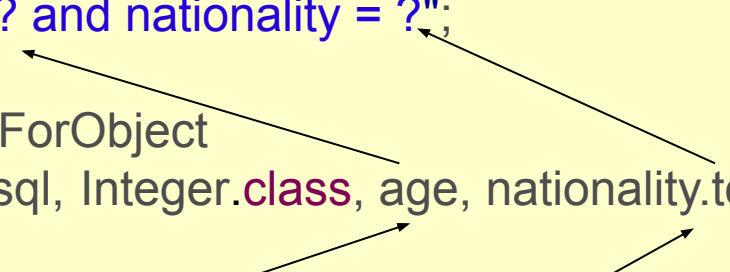

Older alternatives, `queryForInt()`, `queryForLong()`, deprecated and removed since Spring 4.2

Query With Bind Variables

- Can query using bind variables – ?
 - Note the use of a variable argument list

```
private JdbcTemplate jdbcTemplate;  
  
public int getCountOfNationalsOver(Nationality nationality, int age) {  
    String sql = "select count(*) from PERSON " +  
                "where age > ? and nationality = ?";  
  
    return jdbcTemplate.queryForObject  
        (sql, Integer.class, age, nationality.toString());  
}
```

A diagram with two arrows pointing from the question marks in the SQL string to the labels 'Bind to first ?' and 'Bind to second ?' below. The first arrow points from the first '?' to the first label, and the second arrow points from the second '?' to the second label.

Bind to first ?

Bind to second ?

Database Writes (1)

- Inserting a new row
 - Returns number of rows modified

```
public int insertPerson(Person person) {  
    return jdbcTemplate.update(  
        "insert into PERSON (first_name, last_name, age)" +  
        "values (?, ?, ?)",  
        person.getFirstName(),  
        person.getLastName(),  
        person.getAge());  
}
```

Database Writes (2)

- Updating an existing row

```
public int updateAge(Person person) {  
    return jdbcTemplate.update(  
        "update PERSON set age=? where id=?",  
        person.getAge(),  
        person.getId());  
}
```

Any non-SELECT SQL is run using update()

Agenda

- Problems with Traditional JDBC
- Spring's **JdbcTemplate**
 - Introduction
 - Basic Usage
 - **Working with Result Sets**
 - Exception Handling
- Lab
- Optional Slides

Generic Queries

- **JdbcTemplate** can return each row of a **ResultSet** as a **Map**
 - When expecting a single row
 - Use `queryForMap(..)`
 - When expecting multiple rows
 - Use `queryForList(..)`
- Useful for *ad hoc* reporting, testing use cases
 - The data fetched *does not need* mapping to a Java object

ad hoc – created or done for a particular purpose as necessary
– sometimes called “window-on-data” queries

Querying for Generic Maps (1)

- Query for a single row

```
public Map<String,Object> getPersonInfo(int id) {  
    String sql = "select * from PERSON where id=?";  
    return jdbcTemplate.queryForMap(sql, id);  
}
```

- Returns

Map { ID=1, FIRST_NAME="John", LAST_NAME="Doe" }

A Map of [Column Name | Field Value] pairs

Querying for Generic Maps (2)

- Query for multiple rows

```
public List<Map<String,Object>> getAllPersonInfo() {  
    String sql = "select * from PERSON";  
    return jdbcTemplate.queryForList(sql);  
}
```

- Returns

List {

A List of Maps of [Column Name | Field Value] pairs

0 - Map { ID=1, FIRST_NAME="John", LAST_NAME="Doe" }

1 - Map { ID=2, FIRST_NAME="Jane", LAST_NAME="Doe" }

2 - Map { ID=3, FIRST_NAME="Junior", LAST_NAME="Doe" }

}

Domain Object Queries

- Often it is useful to map relational data into domain objects
 - e.g. a `ResultSet` to an `Account`
- Spring's `JdbcTemplate` supports this using a callback approach
- You may prefer to use ORM for this
 - Need to decide between `JdbcTemplate` queries and JPA (or similar) mappings
 - Some tables may be too hard to map with JPA

RowMapper for mapping a row

- Spring provides a **RowMapper** interface for mapping a single row of a **ResultSet** to an object
 - Can be used for both single and multiple row queries
 - Parameterized to define its return-type

```
public interface RowMapper<T> {  
    T mapRow(ResultSet rs, int rowNum) throws SQLException;  
}
```

Querying for Domain Objects (1)

- Query for single row with **JdbcTemplate**

Returns a Domain object

```
public Person getPerson(int id) {  
    return jdbcTemplate.queryForObject(  
        "select first_name, last_name from PERSON where id=?",  
        (rs, rowNum) -> new Person(rs.getString("first_name"),  
                                     rs.getString("last_name")),  
        id);  
}
```

Define RowMapper
using *Lambda*

Alternative implementation using an explicit **RowMapper** subclass is shown at the end of this section.

Querying for Domain Objects (2)

- Query for multiple rows

Returns a List of Domain objects

```
public List<Person> getAllPersons() {  
    return jdbcTemplate.query(  
        "select first_name, last_name from PERSON",  
        (rs, rowNum) -> new Person(rs.getString("first_name"),  
                                     rs.getString("last_name"))  
    );  
}
```

Define RowMapper
using *Lambda*

ResultSetExtractor

- Spring provides a **ResultSetExtractor** interface for processing an entire **ResultSet** at once
 - *You* are responsible for iterating the **ResultSet**
 - *Example:* mapping entire **ResultSet** to a *single* object

```
public interface ResultSetExtractor<T> {  
    T extractData(ResultSet rs) throws SQLException,  
        DataAccessException;  
}
```

You may need this for the lab!

Using a ResultSetExtractor

Using a *lambda*

```
public class JdbcOrderRepository {  
    public Order findByConfirmationNumber(String number) {  
        // Execute an outer join between order and item tables  
        return jdbcTemplate.query(  
            "select...from order o, item i...conf_id = ?",  
            (ResultSetExtractor<Order>)(rs) -> {  
                Order order = null;  
                while (rs.next()) {  
                    if (order == null)  
                        order = new Order(rs.getLong("ID"), rs.getString("NAME"), ...);  
                    order.addItem(mapItem(rs));  
                }  
                return order;  
            },  
            number);  
    }  
}
```

Cast
needed

Summary of Callback Interfaces

- **RowMapper**
 - Best choice when *each* row of a **ResultSet** maps to a domain object
- **ResultSetExtractor**
 - Best choice when *multiple* rows of a **ResultSet** map to a *single* object
- **RowCallbackHandler**
 - Yet another handler that writes to alternative destinations

Agenda

- Problems with Traditional JDBC
- Spring's **JdbcTemplate**
 - Introduction
 - Basic Usage
 - Working with Result Sets
 - **Exception Handling**
- Lab
- Optional Slides

Exception Handling and Spring

- Checked Exceptions
 - Force developers to handle errors
 - But if you can't handle it, must declare it
 - **Bad:** intermediate methods must declare exception(s) from *all* methods below
 - A form of tight-coupling
- Unchecked Exceptions
 - Can throw up the call hierarchy to the best place to handle it
 - **Good:** Methods in between don't know about it
 - Better in an Enterprise Application
 - **Spring always throws Runtime (unchecked) Exceptions**

Data Access Exceptions

- **SQLException**
 - Too general – one exception for every database error
 - Calling class 'knows' you are using JDBC
 - Tight coupling
- Spring provides **DataAccessException** hierarchy
 - Hides whether you are using JPA, Hibernate, JDBC ...
 - Actually a hierarchy of sub-exceptions
 - Not just one exception for everything
 - Consistent across all supported Data Access technologies
 - Unchecked

Example: *BadSqlGrammarException*

Select *iddd* from T_ACCOUNT

Plain JDBC

java.sql.SQLException
Message: Column not found:
IDDD in statement
errorCode: -28

Spring

java.sql.SQLException
Message: Column not found:
IDDD in statement
errorCode: -28

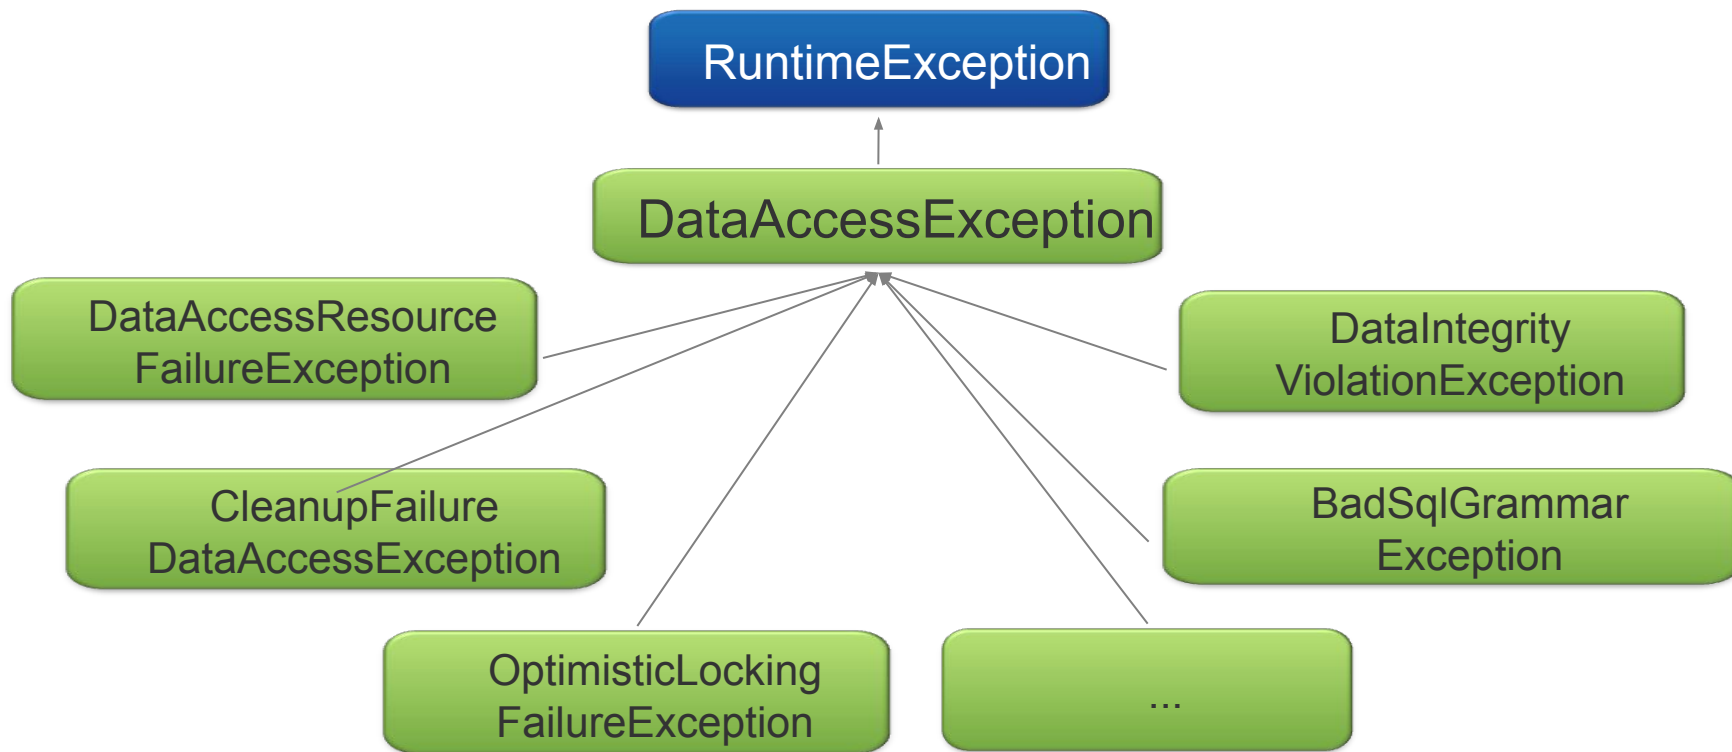

Error code mapping

BadSqlGrammarException
Message: PreparedStatementCallback;
bad SQL grammar ... Column not
found: IDDD in statement

<https://github.com/spring-projects/spring-framework/blob/master/spring-jdbc/src/main/resources/org/springframework/jdbc/support/sql-error-codes.xml>

Spring Data Access Exceptions

Summary

- JDBC is useful
 - But using JDBC API directly is tedious and error-prone
- **JdbcTemplate** simplifies data access and enforces consistency
 - DRY principle hides most of the JDBC
 - Many options for reading data
- **SQLExceptions** typically cannot be handled where thrown
 - Should not be *checked* Exceptions
 - Spring provides ***DataAccessException*** instead

A man with a beard and a woman are sitting at a desk, looking at a computer monitor. The man is pointing at the screen. The background is a blurred office environment.

Lab: JDBC Simplification with JdbcTemplate

**Lab project:
26-jdbc**

**Anticipated Lab time:
45 Minutes**

Optional Topics: Callbacks without Lambdas

Querying for Domain Objects (1)

- Query for single row with JdbcTemplate

```
public Person getPerson(int id) {  
    return jdbcTemplate.queryForObject(  
        "select first_name, last_name from PERSON where id=?",  
        new PersonMapper(), id);  
}
```

No need to cast

Maps rows to Person objects

Parameterizes return type

```
class PersonMapper implements RowMapper<Person> {  
    public Person mapRow(ResultSet rs, int rowNum) throws SQLException {  
        return new Person(rs.getString("first_name"),  
            rs.getString("last_name"));  
    }  
}
```

Querying for Domain Objects (2)

- Query for multiple rows

No need to cast

```
public List<Person> getAllPersons() {  
    return jdbcTemplate.query(  
        "select first_name, last_name from PERSON",  
        new PersonMapper());
```

Same row mapper can be used

```
class PersonMapper implements RowMapper<Person> {  
    public Person mapRow(ResultSet rs, int rowNum) throws SQLException {  
        return new Person(rs.getString("first_name"),  
            rs.getString("last_name"));  
    }  
}
```

ResultSetExtractor *without* a Lambda

```
public class JdbcOrderRepository {  
    public Order findByConfirmationNumber(String number) {  
        // execute an outer join between order and item tables  
        return jdbcTemplate.query(  
            "select...from order o, item i...conf_id = ?",  
            new OrderExtractor(), number);  
    }  
}
```

```
class OrderExtractor implements ResultSetExtractor<Order> {  
    public Order extractData(ResultSet rs) throws SQLException {  
        Order order = null;  
        while (rs.next()) {  
            if (order == null) {  
                order = new Order(rs.getLong("ID"), rs.getString("NAME"), ...);  
            }  
            order.addItem(mapItem(rs));  
        }  
        return order;  
    }  
}
```
