

More Configuration

Deeper Look into Spring's Java Configuration Capability

Objectives

After completing this lesson, you should be able to

- Use External Properties to control Configuration
- Demonstrate the purpose of Profiles
- Use the Spring Expression Language (SpEL)
- Explain How Configuration classes are Manipulated at Runtime

Agenda

- External Properties
- Profiles
- Spring Expression Language
- Singleton "Magic"

Setting property values

Consider this bean definition from the last chapter:

```
@Bean
public DataSource dataSource() {
    BasicDataSource ds = new BasicDataSource();
    ds.setDriverClassName("org.postgresql.Driver");
    ds.setUrl("jdbc:postgresql://localhost/transfer");
    ds.setUser("transfer-app");
    ds.setPassword("secret45");
    return ds;
}
```

- Bad practice to hard-code these parameter Strings
 - Better practice is to "externalize" these to a properties file

Spring's Environment Abstraction – 1

- Environment object used to load properties from runtime environment
- Properties derived from various sources, in this order:
 - JVM System Properties System.getProperty()
 - Servlet Context Parameters
 - JNDI
 - System Environment Variables System.getenv()
 - Java Properties Files

Spring's Environment Abstraction – 2

```
Inject Environment bean
       @Configuration
                                                             like any other Spring Bean
       public class DbConfig {
         @Bean public DataSource dataSource(Environment env) {
          BasicDataSource ds = new BasicDataSource();
                                                                                Fetch property
          ds.setDriverClassName( env.getProperty( "db.driver" ));
                                                                                 values from
          ds.setUrl( env.getProperty( "db.url" ));
          ds.setUser( env.getProperty( "db.user" ));
                                                                                 environment
          ds.setPassword( env.getProperty( "db.password" ));
          return ds;
                              db.driver=org.postgresql.Driver
                              db.url=jdbc:postgresql:localhost/transfer
                              db.user=transfer-app
                              db.password=secret45
                                                                 app.properties
Pivotal
```

Property Sources

- Environment bean obtains values from "property sources"
 - Environment variables and Java System Properties always populated automatically
 - @PropertySource contributes additional properties
 - Available resource prefixes: classpath: file: http:

```
@Configuration
@PropertySource ( "classpath:/com/organization/config/app.properties" )
@PropertySource ( "file:config/local.properties" )
public class ApplicationConfig {

Adds properties from these files in addition to environment variables and system properties
```

Accessing Properties using @Value

```
@Configuration
public class DbConfig {
 @Bean
 public DataSource dataSource(
      @Value("${db.driver}") String driver,
      @Value("${db.url}") String url,
      @Value("${db.user}") String user,
      @Value("${db.password}") String pwd) {
   BasicDataSource ds = new BasicDataSource();
   ds.setDriverClassName( driver);
   ds.setUrl( url);
   ds.setUser( user);
   ds.setPassword( pwd ));
   return ds;
```

Convenient
alternative to
explicitly using
Environment bean

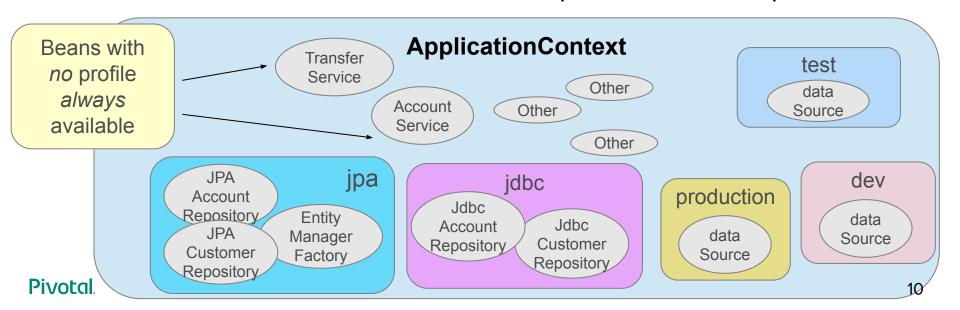

Agenda

- External Properties
- Profiles
- Spring Expression Language
- Singleton "Magic"

Profiles - Beans can be grouped into Profiles

- Profiles can represent environment: dev, test, production
- Or implementation: "jdbc", "jpa"
- Or deployment platform: "on-premise", "cloud"
- Beans included / excluded based on profile membership

Defining Profiles – 1

- Using @Profile annotation on configuration class
 - Everything in Configuration belong to the profile

```
@Configuration
@Profile("embedded")
                                     Nothing in this configuration will be
public class DevConfig {
                                    used unless "embedded" is activated
  @Bean
  public DataSource dataSource() {
    EmbeddedDatabaseBuilder builder = new EmbeddedDatabaseBuilder();
    return builder.setName("testdb")
            .setType(EmbeddedDatabaseType.HSQL)
            .addScript("classpath:/testdb/schema.db")
            .addScript("classpath:/testdb/test-data.db").build();
                                           H2, Derby are also supported
```

Defining Profiles - 2

Using @Profile annotation on @Bean methods

```
@Configuration
public class DataSourceConfig {
                                                Explicit bean-name
  @Bean(name="dataSource") -
                                             overrides method name
  @Profile("embedded")
  public DataSource dataSourceForDev() {
    EmbeddedDatabaseBuilder builder = new EmbeddedDatabaseBuilder();
    return builder.setName("testdb") ...
  @Bean(name="dataSource")
  @Profile("!embedded")
                                                           Both profiles define
  public DataSource dataSourceForProd() {
    BasicDataSource dataSource = new BasicDataSource();
                                                          same bean id, so only
                                                          one profile should be
    return dataSource;
                                                           activated at a time.
```

Pivotal

Defining Profiles - 3

Beans when a profile is not active

```
@Configuration
@Profile("cloud")
                                            If cloud is active profile
public class DevConfig {
@Configuration
                                           If cloud is inactive profile
@Profile("!cloud")
public class ProdConfig {
                               Not cloud – use
                                exclamation!
```

Ways to Activate Profiles

- Profiles must be activated at run-time
 - System property via command-line

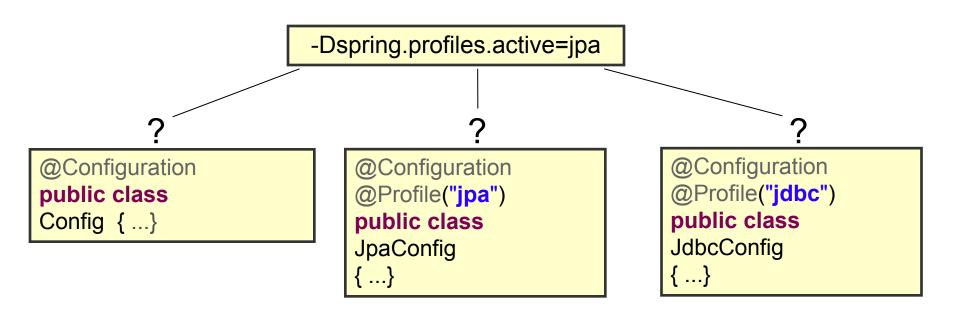

```
-Dspring.profiles.active=embedded,jpa
```

System property programmatically

```
System.setProperty("spring.profiles.active", "embedded,jpa");
SpringApplication.run(AppConfig.class);
```

Integration Test only: @ActiveProfiles (later section)

Quiz: Which of the Following is/are Selected?

Property Source selection

 @Profile can control which @PropertySources are included in the Environment

```
@Configuration
                                              @Configuration
@Profile("local")
                                              @Profile("cloud")
@PropertySource ("local.properties")
                                              @PropertySource ( "cloud.properties" )
class DevConfig { ... }
                                              class ProdConfig { ... }
                                              db.driver=org.postgresql.Driver
db.driver=org.postgresql.Driver
                                              db.url=jdbc:postgresql://prod/transfer
db.url=jdbc:postgresql://localhost/transfer
                                              db.user=transfer-app
db.user=transfer-app
                                              db.password=secret99
db.password=secret45
                         local.properties
                                                                        cloud.properties
```

Agenda

- External Properties
- Profiles
- Spring Expression Language
- Singleton "Magic"

Spring Expression Language

- SpEL for short
 - Inspired by the Expression Language used in Spring WebFlow
 - Based on Unified Expression Language used by JSP and JSF
- Pluggable/extendable by other Spring-based frameworks

This is just a brief introduction, for full details see: http://docs.spring.io/spring/docs/current/spring-framework-reference/html/expressions.html

SpEL examples – Using @Value

```
@Configuration
class TaxConfig {
  @Value("#{ systemProperties['user.region'] }") String region;
  @Bean
                                                             Option 1: Set an
  public TaxCalculator taxCalculator1() {
                                                            attribute then use it
    return new TaxCalculator( region );
  @Bean
  public TaxCalculator taxCalculator2
          (@Value("#{ systemProperties['user.region'] }") String region, ...) {
    return new TaxCalculator( region );
                                                         Option 2: Pass as a
                                                        bean method argument
```

SpEL – Accessing Spring Beans

```
class StrategyBean {
   private KeyGenerator gen = new KeyGenerator.getInstance("Blowfish");
   public KeyGenerator getKeyGenerator() { return gen; }
      @Configuration
      class StrategyConfig
         @Bean public StrategyBean strategyBean() {
             return new StrategyBean();
              @Configuration
              @Import(StrategyConfig.class)
              class AnotherConfig
                  @Value("#{strategyBean.keyGenerator}") KeyGenerator kgen;
Pivotal
```

Accessing Properties

- Can access properties via the environment
 - These are equivalent

```
@Value("${daily.limit}")
int maxTransfersPerDay;
```

@Value("#{environment['daily.limit']}")
int maxTransfersPerDay;

- Properties are Strings
 - May need to cast in expressions

```
@Value("#{new Integer(environment['daily.limit']) * 2}")
@Value("#{new java.net.URL(environment['home.page']).host}")

Cannot do this with properties
```

Fallback Values

- Providing a fall-back value
 - If daily.limit undefined, use colon:

```
@Autowired
public TransferServiceImpl(@Value("${daily.limit : 100000}") int max) {
  this.maxTransfersPerDay = max;
                                                          Equivalent operators
      For SpEL, use the "Elvis" operator ?:
@Autowired
public setLimit(@Value("#{environment['daily.limit'] ?: 100000}") int max) {
   this.maxTransfersPerDay = max;
                               x ?: y is short for x != null ? x : y
```

SpEL

- EL Attributes can be:
 - Spring beans (like strategyBean)
 - Implicit references
 - Spring's environment, systemProperties, systemEnvironment available by default
 - Others depending on context
- SpEL allows to create custom functions and references
 - Widely used in Spring projects
 - Spring Security, Spring WebFlow
 - Spring Batch, Spring Integration
 - Each may add their own implicit references

Agenda

- External Properties
- Profiles
- Spring Expression Language
- Singleton "Magic"

Quiz

```
Which is the best
@Bean
                                                  implementation?
public AccountRepository accountRepository() {
  return new JdbcAccountRepository();
@Bean
                                                     1. Method call?
public TransferService transferService1() {
  TransferServiceImpl service = new TransferServiceImpl();
  service.setAccountRepository(accountRepository());
  return service:
                                                     2. New instance?
@Bean
public TransferService transferService2() {
  return new TransferServiceImpl( new JdbcAccountRepository() );
       Prefer call to dedicated method. Let's discuss why
```

Pivotal

Working with Singletons

```
Recall: Singleton is default scope
@Bean
public AccountRepository accountRepository() {
  return new JdbcAccountRepository();
                                                        Singleton??
@Bean
public TransferService transferService() {
  TransferServiceImpl service = new TransferServiceImpl();
  service.setAccountRepository(accountRepository());
                                                            Method
  return service:
                                                         called twice
                                                             more
@Bean
public AccountService accountService() {
  return new AccountServiceImpl( accountRepository() );
                         HOW IS IT POSSIBLE?
```

Singletons Require "Magic"

- At startup time, a subclass is created
 - Subclass performs scope-control
 - Only calls super on first invocation of singleton bean method
 - Singleton instance is cached by the ApplicationContext

```
@Configuration
public class AppConfig {
    @Bean public AccountRepository accountRepository() { ... }
    @Bean public TransferService transferService() { ... }
}
```

→ inherits from

```
public class AppConfig$$EnhancerByCGLIB$ extends AppConfig {
   public AccountRepository accountRepository() { // ... }
   public TransferService transferService() { // ... }
}
```

Inheritance-based Subclasses

Child class is the entry point

```
public class AppConfig$$EnhancerByCGLIB$ extends AppConfig {
 public AccountRepository accountRepository() {
  // if bean is in the applicationContext, then return bean
  // else call super.accountRepository(), store bean in context, return bean
 public TransferService transferService() {
  // if bean is in the applicationContext, then return bean
  // else call super.transferService(), store bean in context, return bean
```

Java Configuration uses *cglib* for inheritance-based subclasses

Summary

- Property values are easily externalized using Spring's Environment abstraction
- Profiles are used to group sets of beans
- Spring Expression Language
- Spring proxies your @Configuration classes to allow for scope control
